Fortunately, there is a chance you might be able to determine whether or not you unit is going to fail for good by looking at a few indicators. If your MCU is too old or if you're using a Xilinx XC7S90T, check out the following indicators and you might be able to stop it from failing: Your MCU flashes random bits too often If you have an MCU with the A20 pin connected to the MCU's reset pin, then it is not possible to have a "real" safe mode. So if your MCU flashes random bits too often, then there is a good chance it is not going to work even when you do have your MCU's reset pin connected to an XC7S90T's A20 pin. (Note: if it does, then double check that you have reset the MCU's A20 pin to 0v) The MCU is too old If the MCU is way too old, then the likelihood of it failing when exposed to extreme situations, such as those you would face when hosting an MCU, is much higher. The MCU is using MCU very low voltages (Vcc) MCUs don't always work f678ea9f9e
